Summary

Solving the Bethe-Salpeter Equation (BSE) is essential for understanding excited-state systems, but often challenging to converge or even computationally prohibitive for large systems. We implement a matrix-free BSE solver leveraging Interpolative Separable Density Fitting (ISDF) to interpolate electron-hole interaction kernels together with the Lanczos algorithm for diagonalization, avoiding full matrix setup. The scaling of our implementation is bounded by $\mathcal{O}(N_o N_u N_k \log N_k)$ and is thus a massive improvement over methods that set up the whole matrix, scaling with at least $\mathcal{O}((N_o N_u N_k)^3)$, where N_o and N_u are the numbers of occupied and unoccupied states, respectively, and N_k is the number k -points.

Theoretical background

The Bethe-Salpeter Equation (BSE) within many body perturbation theory (MBPT) provides the state-of-the-art frame work for describing light-matter interaction. In particular, it is used to obtain optical absorption spectra, including the effects of excitons, which are bound electron-hole states. By expanding the electron-hole wavefunctions in the transition basis, solving the BSE can be reduced to a Schrödinger like equation. Setting up and diagonalizing the Bethe-Salpeter Hamiltonian (BSH) are the computationally expensive tasks (Vorwerk et al., 2019). The BSH is given as

$$H^{BSH} = D + \gamma V - W,$$

where $\gamma = 2$ gives the spin-singlet and $\gamma = 0$ spin-triplet channel, respectively. The diagonal term D is given by the differences of the one-particle energies of the occupied (o) and unoccupied (u) states:

$$D_{ouk,o'u'k'} = (\varepsilon_{uk} - \varepsilon_{ok}) \delta_{oo'} \delta_{uu'} \delta_{kk'}.$$

The matrix elements of the repulsive exchange interaction V and the attractive screened Coulomb interaction W are calculated by solving integrals of the form

$$V_{ouk,o'u'k'} = \int d^3r \int d^3r' \frac{u_{ok}(\mathbf{r}) u_{uk}^*(\mathbf{r}) u_{o'k'}^*(\mathbf{r}') u_{u'k'}(\mathbf{r}')}{|\mathbf{r} - \mathbf{r}'|},$$

$$W_{ouk,o'u'k'} = \int d^3r \int d^3r' u_{uk}^*(\mathbf{r}) u_{u'k'}(\mathbf{r}) W_{k-k'}(\mathbf{r}, \mathbf{r}') u_{ok}(\mathbf{r}') u_{o'k'}^*(\mathbf{r}'),$$

where $W_{k-k'}(\mathbf{r}, \mathbf{r}')$ is the statically screened Coulomb potential. $u_{ik}(\mathbf{r})$ is the periodic part of the one-particle wavefunction of state i at the reciprocal lattice point $\mathbf{k}$. In general, we cannot see, which of the matrix elements will be zero, thus we need to compute all of them. Therefore, setting up the full BSH scales with $\mathcal{O}(N_o^2 N_u^2 N_k^2)$ and diagonalizing it directly with $\mathcal{O}(N_o^3 N_u^3 N_k^3)$.

33 The primary scaling bottleneck stems from evaluating the matrix elements of the interaction
 34 kernels. To mitigate this, we reformulate the wavefunction products using Interpolative
 35 Separable Density Fitting (ISDF) (Lu & Ying, 2015). Specifically, we approximate these
 36 products on a discrete real-space grid, $\{\mathbf{r}\}$, by expressing them as superpositions of values
 37 evaluated on a smaller interpolation grid, $\{\mathbf{r}_\mu\} \subset \{\mathbf{r}\}$:

$$u_{ik}^*(\mathbf{r})u_{jk'}(\mathbf{r}) \approx \sum_{\mu=1}^{N_\mu} \zeta_\mu(\mathbf{r})u_{ik}^*(\mathbf{r}_\mu)u_{jk'}(\mathbf{r}_\mu),$$

38 where N_μ is the number of interpolation points, and $\zeta_\mu(\mathbf{r})$ are the expansion coefficients.
 39 Due to the tensor product structure of $u_{ik}^*(\mathbf{r})u_{jk'}(\mathbf{r})$, $\zeta_\mu(\mathbf{r})$ can be computed efficiently, and
 40 the scaling is bounded by $\mathcal{O}(N_\mu^3)$ (Hu et al., 2017). We observe that we can always choose
 41 $N_\mu \ll N_o N_u N_k$, thus ISDF is never a bottleneck. The interpolation points are computed
 42 efficiently with centroidal Voronoi tessellation within $\mathcal{O}(N_\mu N_r)$ (Dong et al., 2018).

43 Inserting ISDF in the equations for the interaction kernels yields

$$V_{ouk,o'u'k'} \approx \frac{1}{N_k^2} \sum_{\mu=1}^{N_\mu^V} \sum_{\nu=1}^{N_\mu^V} u_{ok}(\mathbf{r}_\mu^V)u_{uk}^*(\mathbf{r}_\mu^V)\tilde{V}_{\mu\nu}u_{o'k'}^*(\mathbf{r}_\nu^V)u_{u'k'}(\mathbf{r}_\nu^V),$$

$$W_{ouk,o'u'k'} \approx \frac{1}{N_k^2} \sum_{\mu=1}^{N_\mu^{W_u}} \sum_{\nu=1}^{N_\mu^{W_o}} u_{uk}^*(\mathbf{r}_\mu^{W_u})u_{u'k'}(\mathbf{r}_\mu^{W_u})\tilde{W}_{\mu\nu,k-k'}u_{ok}(\mathbf{r}_\nu^{W_o})u_{o'k'}^*(\mathbf{r}_\nu^{W_o}),$$

45 where we have shifted the integration from the wavefunction pairs to the interpolation
 46 coefficients such that

$$\tilde{V}_{\mu\nu} = \int_{\Omega^l \times \Omega^l} d\mathbf{r}d\mathbf{r}' \zeta_\mu^* V(\mathbf{r})V(\mathbf{r}')\zeta_\nu(\mathbf{r}'),$$

$$\tilde{W}_{\mu\nu,k-k'} = \int_{\Omega^l \times \Omega^l} d\mathbf{r}d\mathbf{r}' \zeta_\mu^* W_{k-k'}(\mathbf{r},\mathbf{r}')\zeta_\nu^{W_o}(\mathbf{r}').$$

48 Note that there are three different wavefunction pairings, i.e. $u_{ok}^*(\mathbf{r})u_{uk}(\mathbf{r})$ for the exchange
 49 kernel (V) and $u_{ok}^*(\mathbf{r})u_{o'k'}(\mathbf{r})$, $u_{uk}^*(\mathbf{r})u_{u'k'}(\mathbf{r})$ for the screened kernel W . Each pairing
 50 requires a separate ISDF calculation, denoted by the superscripts V , W_o , and W_u . Since
 51 the number of combinations may vary, the number of interpolation points required may also
 52 vary. Reformulating the matrix elements in this way alone does not improve scaling with
 53 respect to the system size. To achieve this, we combine it with an iterative solver, here
 54 with the Lanczos algorithm. This class of algorithms constructs an approximation to the
 55 eigenvalues and eigenvectors by iteratively applying matrix-vector multiplications. Applying
 56 the interaction kernels in their interpolated forms to a vector X of dimension $N_o N_u N_k$ allows
 57 efficient computation by rearranging the summations to exploit a separable structure of the
 58 kernels. For the exchange kernel we get

$$[V \cdot X]_{ouk} = \frac{1}{N_k} \sum_{\mu=1}^{N_\mu^V} u_{uk}^*(\mathbf{r}_\mu^V)u_{ok}(\mathbf{r}_\mu^V) \left\{ \sum_{\nu=1}^{N_\mu^V} \tilde{V}_{\mu\nu} \left[\sum_{k'} \left(\sum_{u'} u_{u'k'}(\mathbf{r}_\nu^V) \left[\sum_{o'} u_{o'k'}^*(\mathbf{r}_\nu^V) \cdot X_{o'u'k'} \right] \right) \right] \right\},$$

59 where we first compute the sums over o' , u' , and k' to get a term that depends only on $\mathbf{r}_\nu^V$
 60 with a complexity of $\mathcal{O}(N_\mu^V(N_o N_u N_k + N_u N_k))$. The remaining sums can be computed with
 61 $\mathcal{O}((N_\mu^V)^2 N_\mu^V N_o N_u N_k)$, so the complexity of computing $V \cdot X$ is bounded by $\mathcal{O}((N_\mu^V)^2 +$
 62 $N_\mu N_o N_u N_k)$. Applying the screened kernel to X , after reordering the sums, we get

$$[W \cdot X]_{ouk} = \frac{1}{N_k} \sum_{\nu=1}^{N_\mu^{W_o}} u_{ok}(\mathbf{r}_\nu^{W_o}) \left\{ \sum_{\mu=1}^{N_\mu^{W_u}} u_{uk}^*(\mathbf{r}_\mu^{W_u}) \left[\sum_{k'} \tilde{W}_{\mu\nu,k-k'} \left(\sum_{u'} u_{u'k'}(\mathbf{r}_\mu^{W_u}) \left[\sum_{o'} \right. \right. \right. \right. \right.$$

63

$$u_{o'k'}^*(\mathbf{r}_{\nu}^{W_o})X_{o'u'k'} \}} \} .$$

64 Here we exploit the separable structure of the decomposition so that the terms depending on
 65 $\mathbf{k}$ and $\mathbf{k}'$ are on the left and right of $\tilde{W}_{\mu\nu, \mathbf{k}-\mathbf{k}'}$. The evaluation of the two innermost sums
 66 over o' and u' to $A_{\mu\nu}^{k'}$ scales with $\mathcal{O}(N_{\mu}^{W_u} N_o N_u N_{\mathbf{k}} + N_{\mu}^{W_o} N_{\mu}^{W_u} N_u N_{\mathbf{k}})$. Then the sum over
 67 $\mathbf{k}'$ reads as a discrete convolution

$$\sum_{\mathbf{k}'} W_{\mathbf{k}-\mathbf{k}'} A_{\mu\nu}^{k'} ,$$

68 which can be efficiently evaluated with fast Fourier transforms simultaneously within
 69 the $\mathcal{O}(N_{\mathbf{k}} \log N_{\mathbf{k}})$ scaling for each $\mu\nu$ pair. The remaining summations scale with
 70 $\mathcal{O}(N_{\mu}^{W_o} N_{\mu}^{W_u} N_u N_{\mathbf{k}})$. So the complexity for the computation of $W \cdot X$ is bounded by
 71 $\mathcal{O}(N_{\mu}^{W_u} N_o N_u N_{\mathbf{k}} + N_{\mu}^{W_o} N_{\mu}^{W_u} N_u N_{\mathbf{k}} + N_{\mu}^{W_o} N_{\mu}^{W_u} N_{\mathbf{k}} \log N_{\mathbf{k}})$.

72 Statement of need

73 Due to the unfavorable scaling of solving the BSE directly, many interesting problems such as
 74 complex materials with large unit cells or systems requiring a dense Brioullin-zone sampling
 75 are not feasible. Even though Henneke and coworkers (Henneke et al., 2020) have already
 76 described the new algorithm and demonstrated the scaling improvement, an easy-to-use and
 77 scalable implementation was still missing. We have implemented and fully integrated this
 78 approach in the existing BSE infrastructure of the all-electron, full-potential package exciting
 79 (Gulans et al., 2014). Users can now easily choose which algorithm they prefer to use and
 80 have the full suite of exciton analysis implemented in exciting at hand.

81 Results

82 To demonstrate that our implementation does indeed scale as proposed, we run BSE calculations
 83 for increasing $N_{\mathbf{k}}$ using the direct and the new implementation. In Fig.(Figure 1) we show the
 84 wall times for the example of diamond. The new algorithm massively outperforms the direct,
 85 and the speed up increases more than linearly with $N_{\mathbf{k}}$.

Figure 1: Runtimes of the RPA screening (blue) and the direct (black) and new (red) BSE implementations as a function of the number of k-points, N_k . The speedup of the algorithm is shown by the gray line.

In Fig.(Figure 2) we show the differences in exciton binding energies obtained from the direct implementation, which sets up and diagonalizes the full BSH, and the new implementation with fixed numbers of interpolation points: $N_\mu^V = 202$, $N_\mu^{W_o} = 322$, and $N_\mu^{W_u} = 360$ for the ISDF. Additionally, we present the spectral similarity, defined here as the area between the two curves. Even with these fixed numbers of interpolation points, the results of the new algorithm converge to those of the direct algorithm as N_k increases. This demonstrates that the new implementation yields results equivalent to the direct solution of the BSE but with significantly reduced computational time. Consequently, it enables more precise calculations and facilitates the study of more complex problems.

Figure 2: Difference of the exciton binding energy and spectral similarity between the new method and the direct method as functions of N_k for the case of diamond.
